

Coding Theory

The process of communication involves transmitting some information carrying signal (message) that is conveyed by a sender to a receiver.

Coding theory deals with minimizing the distortions of the conveyed message due to noise and to relieve the original message to the optimal extent possible from the corrupted message.

Encoder: An encoder is a device which transforms the incoming message in such a way that the presence of noise in the transformed messages is detectable.

Decoder: A decoder is a device which transforms the encoded message into their original form that can be understood by the receiver.

- * We will use only a binary channel in which the encoder will transform an input message into a binary string consisting of the symbols 0 and 1.
- * Decoding is only the inverse operation of encoding.

GROUP CODE:

$$B = \{0, 1\}, \text{ then } B^n = \{x_1, x_2, \dots, x_n \mid x_i \in B\}$$

is a group under the binary operation of addition modulo 2, denoted by \oplus . This group (B^n, \oplus) is called a group code.

Proof

$$\text{If } x_1, x_2, \dots, x_n = (x_1, x_2, x_3, \dots, x_n)$$

$$\text{and } y_1, y_2, \dots, y_n = (y_1, y_2, y_3, \dots, y_n) \in B^n$$

$$\text{Then } x_1 \oplus x_2, x_2 \oplus x_3, \dots, x_n \oplus y_1, y_2, \dots, y_n$$

$$= (x_1 +_2 y_1, x_2 +_2 y_2, \dots, x_n +_2 y_n) \in B^n$$

$$\text{Since } x_i +_2 y_i = 1 \text{ or } 0 \text{ as } 0 +_2 0 = 0$$

$$0 +_2 1 = 1$$

$$1 +_2 0 = 1, 1 +_2 1 = 0.$$

$(0, 0, 0, \dots, 0)$ is the identity element of B^n .

The inverse of x_1, x_2, \dots, x_n is itself

$$[\because (x_1, \dots, x_n) + (x_1, \dots, x_n) = (0, 0, \dots, 0)]$$

$\therefore (B^n, \oplus)$ is a group - It is also a abelian group.

* In general, any code which is a group under the operation \oplus is called a group code.

HAMMING CODE:

The codes obtained by introducing additional digits called parity digits to the digits in the original message is a binary string of length ' m ', the Hamming encoded message is a string of length ' n ' ($n > m$) of n digits, m digits are used to represent the information part of the message and the remaining $(n-m)$ digits are used for the detection and correction of errors in the received message.

HAMMING SINGLE ERROR DETECTING CODE:

It is a code of length ' n ', the first $(n-1)$ digits contain the information part of the message and the last digit is made either 0 or 1.

Odd Parity / even Parity

If the digit introduced in the last (portion) position gives an even number of count 1's / odd number of count 1's in the encoded word of length n , then extra digit is called an even/odd parity check.

Examples:

words	000	0 0 1	0 1 1
even parity	0000	0011	0110

words	0 0 0	0 0 1	0 1 1
odd parity	0 0 0 1	0 0 1 0	0 1 1 1

Weight of a code:

The number of 1's in the binary string $x \in B^n$ is called the weight of code ' x '. and denoted by $|x|$

$$x = 110101101 \Rightarrow |x| = 6.$$

Hamming distance $H(x,y)$

If x and y represents the binary strings x_1, x_2, \dots, x_n and y_1, y_2, \dots, y_n the number of positions in the strings for which $x_i \neq y_i$ is called the Hamming distance between x and y denoted by $H(x,y)$

$$\therefore H(x,y) = \text{weight of } x \oplus y = \sum_{i=1}^n (x_i + y_i)$$

Example: If $x = 11010$ $y = 10101$

$$H(x,y) = |x \oplus y| = |01111| = 4.$$

Minimum distance:

The minimum distance of a code is the minimum of the Hamming distances between all pairs of encoded words in that code.

Example

If $x = 10110$, $y = 11110$, $z = 10011$

$$H(x,y) = |x \oplus y| = |01000| = 1$$

$$H(y,z) = |y \oplus z| = |01101| = 3$$

$$H(z,x) = |z \oplus x| = |00101| = 2$$

So the minimum distance between the code words
is $\boxed{1}$, is the Hamming distances.

THEOREM

A code (an (m,n) encoding f_n) can detect at most ' k ' errors if and only if the minimum distance between any two code words is at least $(k+1)$.

Encoding

$$e: B^m \rightarrow B^n, \text{ where } m, n \in \mathbb{Z}^+, n > m$$

encoding function: e is given by a matrix $(m \times n)$
G over B.

ERROR CORRECTION Using MATRICES.

The matrix G_1 is called the generator matrix for the code

$$G_1 = [I_m \mid A]$$

I_m is the identity matrix /
(or) Unit matrix of
order $m \times m$.

I_m - order $m \times m$

A - order $(m) \times (n-m)$.

If w is a message (original message) $\in B^n$.

Then $e(w) = wG_1$ [encoding]

The code $c = e(B^m) \subseteq B^n$, where w is a
 $B = \{0, 1\}$ $(1 \times m)$ vector.

$$B^2 = \{00, 01, 10, 11\}$$

$$B^3 = \{000, 001, 010, 100, 011, 101, 110, 111\}$$

DECODING

For Decoding we need Parity check matrix H .

$$H = [A^T \mid I_{n-m}]$$

H is a $(n-m) \times m$ matrix

G is a $m \times n$ matrix

I_m is a $m \times m$ Unit matrix

A is a $m \times (n-m)$ matrix suitably chosen.

r is a $1 \times n$ matrix.

r - is the received message.

- * This Unique Parity check matrix H provides a decoding scheme that corrects a single error in transmission as explained below.

Case (i): If ' r ' is a received word considered as $(1 \times n)$ matrix and if

$H \cdot r^T = [0]$, then we conclude that there is no error in transmission and that r is the code word transmitted.

Case (ii)

If $H \cdot r^T = i^{\text{th}}$ column of H , then

We conclude that a single error has occurred during transmission. and it has occurred in the i^{th} component of r , changing the i^{th} component of r , we get the code word ' c ' transmitted.

* The first ' m ' components of ' c ' gives the original message.

* Note: $H \cdot r^T =$ the first column of H , a single error has occurred in the first component of ' r '.

Case (ii) If neither Case (i) nor Case (ii) covers them, we conclude that more than one transmission error have occurred. Though detection of error is possible in this case, correction is not possible.

Theorem : 2

A code can correct a set of at most k errors if and only if minimum distance between any two code words is atleast $(2k+1)$.

Problem: 1 Find the code words for $w \in B^2$

assume that $G_1 = \begin{bmatrix} 1 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix}$

Given $w \in B^2 \quad B^2 = \{00, 01, 10, 11\}$

$$w \cdot k \cdot T \quad e(w) = w \cdot G_1$$

$$e(00) = [0 \ 0] \begin{bmatrix} 1 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix} = [0 \ 0 \ 0 \ 0 \ 0]$$

$$e(01) = [0 \bullet 1] \begin{bmatrix} 1 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix} = [01 \ 011]$$

$$e(10) = [1 \circ 0] \begin{bmatrix} 1 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix} = [10 \ 110]$$

$$e(11) = [1 \ 1] \begin{bmatrix} 1 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix} = [111 \ 01]$$

②

Find the Code words generated by the encoding function $e: B^2 \rightarrow B^5$ with respect to the Parity check matrix

$$H = \begin{bmatrix} 0 & 1 & 1 \\ 0 & 1 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\text{W.K.T } e: B^m \rightarrow B^n, \quad m=2, n=5, \quad n-m=3.$$

$$G = [I_m | A] = [I_2 | A]$$

$$H = [A^T | I_{n-m}] = [A^T | I_3]$$

Here in the Problem H^T is given we have to

Rewrite

$$H = \left[\begin{array}{cc|ccc} 0 & 0 & 1 & 0 & 0 \\ 1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{array} \right]_{3 \times 5} = [A^T | I_3]$$

$$A^T = \begin{bmatrix} 0 & 0 \\ 1 & 1 \\ 1 & 1 \end{bmatrix} \quad G = \left[I_2 \mid A \right]$$

$$G = \left[\begin{array}{c|ccccc} 1 & 0 & | & 0 & 1 & 1 \\ 0 & 1 & | & 0 & 1 & 1 \end{array} \right]$$

$$B^2 = \{00, 01, 10, 11\} \quad w.k.t \quad e(\omega) = \omega \cdot G$$

$$e(00) = [00] \begin{bmatrix} 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix} = [00000]$$

$$e(01) = [01] \begin{bmatrix} 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix} = [01011]$$

$$e(10) = [10] \begin{bmatrix} 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix} = [10011]$$

$$e(11) = [11] \begin{bmatrix} 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 \end{bmatrix} = [11000]$$

Hence the Code words generated by H are

00000, 01011, 10011, 11000.

Problem: 3

Find the Code words generated by the Parity check matrix

$$H = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

When the encoding function
is $e: B^3 \rightarrow B^6$.

$$e: B^m \rightarrow B^n, m=3, n=6, n-m=6-3=3.$$

H is not in the correct form. (Taking transpose)

$$H = \left[\begin{array}{ccc|ccc} 1 & 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 \end{array} \right] = [A^T | I_{n-m}] = [A^T | I_3]$$

$$G = [I_m | A] = [I_3 | A] = \left[\begin{array}{ccc|ccc} 1 & 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 & 0 \end{array} \right]$$

$$B^3 = \{000, 001, 010, 100, 011, 101, 110, 111\}$$

$$e(000) = [000] G = [000 \ 000]$$

$$e(001) = [001] G = [001 \ 011]$$

$$e(010) = [010] G = [010 \ 101]$$

$$e(011) = [011] G = [011 \ 110]$$

$$e(100) = [100] G = [100 \ 111]$$

$$e(101) = [101]G = [101100]$$

$$e(110) = [110]G = [110010]$$

$$e(111) = [111]G = [111001]$$

∴ The generated code words are

000000, 001011, 010101, 100111, 011110

1001100, 110010. and 111001.

Problem:4 Given the generator matrix

$$G = \begin{bmatrix} 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 & 1 \end{bmatrix} \text{ corresponding to the}$$

Encoding function $e: B^3 \rightarrow B^6$, find the corresponding Parity check matrix and use it to decode the following received words and hence, to find the original message. Are all words decoded uniquely?

- (i) 110101 (ii) 001111 (iii) 110001
- (iv) 111111

given $e : B^3 \rightarrow B^6$ $m=3, n=6, n-m=3$.

$$G = \left[\begin{array}{ccc|cc} 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 & 1 \end{array} \right] = [I_3 | A]$$

$$H = [A^T | I_{n-3m}] = [A^T | I_3] = \left[\begin{array}{ccc|ccc} 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 \end{array} \right]$$

— x — x —

we Compute the Syndrome of each of the received word by using $H \cdot [r]^T$

$$(i) H \cdot [r]^T = \left[\begin{array}{ccc|ccc} 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 \end{array} \right] \cdot \left[\begin{array}{c} 1 \\ 0 \\ 1 \\ 0 \\ 1 \\ 0 \end{array} \right] = \left[\begin{array}{c} 0 \\ 0 \\ 0 \end{array} \right]$$

$$r = [1 \ 1 \ 0 \ 1 \ 0 \ 1]$$

$r \rightarrow$ received message.

$$\text{Since } H \cdot [r]^T = H \cdot [e(\omega)]^T = \left[\begin{array}{c} 0 \\ 0 \\ 0 \end{array} \right]$$

The received word in this case is the transmitted word

itself

Hence the original message is 110

[* [Since size of m is 3] take first 3 letters]

$$(ii) r = [0 \ 0 \ 1 \ 1 \ 1]$$

$$H \cdot [r]^T = \begin{bmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ - \\ - \\ - \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}$$

Since the Syndrome $\begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}$ is same as the 5th column of H,

∴ The element in the fifth position of 'r' is changed.

∴ The decoded word is $0 \ 0 \ 1 \ 1 \ 0 \ 1$ and the original message is $\boxed{0 \ 0 \ 1}$ [since m=3]

$$(iii) r = 110001$$

$$H \cdot [r]^T = \begin{bmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ - \\ - \\ 0 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

Since the Syndrome $\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$ is the same as the 4th column of H,

The element in the 4th position of 'r' is changed.

The decoded word 110101 and the original message is $\boxed{110}$

$$(iv) r = [1 \ 1 \ 1 \ 1 \ 1 \ 1]$$

$$H \cdot [r]^T = \begin{bmatrix} 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Since the Syndrome $\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$ is not identical to any column of H ,

The received word cannot be decoded uniquely.

Problem: 5 Construct the decoding table for the group code given by the generator matrix

$$G = \begin{bmatrix} 1 & 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 & 1 \end{bmatrix}$$

Decode the following words received using the decoding table obtained. Which of the words could not be decoded uniquely?

~~101111, 011010, 101110, 111111~~

Given $G = \begin{bmatrix} \quad \end{bmatrix}_{3 \times 6} = \begin{bmatrix} I_3 & A \end{bmatrix}$

$m=3, n=6$ since $e: B^3 \rightarrow B^6$.

$B^3 = \{ \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \dots, \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \}$

$e(\omega) = \omega, G$

$$e(000) = [000]G = [000000]$$

$$e(001) = [001]G = [001011]$$

$$e(010) = [010]G = [010101]$$

$$e(100) = [100]G = [100111]$$

$$e(011) = [011]G = [011110]$$

$$e(101) = [101]G = [101100]$$

$$e(110) = [110]G = [110010]$$

$$e(111) = [111]G = [111001]$$

Code words

→	000000	001011	010101	100111	011110	101100	110010	111001
⊕	100000	101011	110101	000111	111110	001100	010010	011001
⊕	010000	011011	000101	111011	000110	001110	000010	010001

⊕	000000	001001	010101	100110	011111	101110	110000	111000
↑	Coset leaders							

for 8th row we can choose '11000', But it is already in 7th row
7th column.

So we choose '01100'.

The decoding table is not unique Since for 8th row we can choose

100001
000110

Recall Theorem

A code can correct a set of at the most k errors if and only if the minimum distance between any two code words is at least $(2k+1)$.

Theorem

In a group code, the minimum distance between distinct code words is the minimum weight of the non zero code words in it.

Example: 10111, 011010, 101110, 11111

minimum weight : 3

from above theorem: $2k+1 = 3$

$$2k = 2 \quad \boxed{k=1}$$

\therefore At most one error can be corrected.

[that is zero or one error can be corrected]

DECODING OF THE RECEIVED WORDS:-

101111, 011010, 101110, 111111

We note that minimum distance between the group codes is minimum weight of the non-zero code words. That is $\boxed{3}$ Here.

\therefore At most 1 error can be corrected

$$\begin{aligned}2k+1 &= 3 \\2k &= 2 \\k &= 1\end{aligned}$$

D) 101111

101111 appears in 4th row and 4th column.

The coset leader of the 4th row is 001 000, which contains only one 1.

The corrected (received) word, the code word transmitted is the top element of the 4th column.

It is 100 111 and hence the original message is $\boxed{100}$

(ii) 011010

011010 appears in 5th row and 5th column

Hence the Corresponding code word transmitted
is 011110 and hence the original message

is 011

(iii) 101110

101110 appears in 6th row and 6th column

Hence the corresponding code word transmitted
is 101100 and hence the original message

is 101

(iv) 111111

111111 appears in 8th row,

The coset leader of which contains two 1's.

The received word has 2 errors.

Hence, it cannot be corrected and the code

word transmitted cannot be Uniquely determined
